Re: Fungal Air Sampling Results  
450 "N" Street, Sacramento, CA 95814  
LaCroix Davis LLC Project No. 1799-393

Dear Mr. Chen:

As you know, LaCroix Davis, LLC (LCD) conducted fungal air sampling in the above referenced property on January 7, 2006. The air sampling was performed on the following ten floors: 2, 3, 7, 9, 11, 15, 18, 20, 22, and 24. LCD performed a visual inspection on these floors with photo documentation, collected non-viable fungal air samples, and recorded temperature/relative humidity measurements.

***Background – Water Intrusion History***

According to Mr. Vincent Paul, Manager of Building and Property Management Branch – Environmental Safety and Health Operations Program (BPM-ESOP), 450 "N" Street has had historic water intrusion related to building envelope failure. McGinnis Chen Associates, Inc. (MCA) requested that LCD perform fungal air sampling to assess the air quality in the building prior to the anticipated window/spandrel repair project. LCD reviewed the previous two years of fungal air sampling reports provided by BPM-ESOP. The BPM-ESOP reports summarized the fungal air sampling performed on floors 2, 3, 11, 22, and 24. These floors, according to Mr. Paul, have had more water intrusion (e.g., water stained ceiling tiles) and occupant complaints related to water intrusion than the other floors in the building.

***Fungal Assessment – January 7, 2006***

Mr. Benjamin J. Heckman and Ms. Christina C. Ross, of LCD, performed a visual inspection with photo documentation, discussed the history of water intrusion with building maintenance personnel, collected non-viable fungal air samples, and recorded temperature/relative humidity measurements on January 7, 2006. Air sampling was performed on ten (floors 2, 3, 7, 9, 11, 15, 18, 20, 22, and 24) of the twenty-three floors in the building.

The sampling selection involved the five floor that have historically had more observed water intrusion/occupant complaints plus five additional floors throughout the building. Four samples were collected per floor on the north, south, east, and west sides of the building. The specific locations on each floor involved sampling along the opposite curtain wall (e.g., north and south) and interior spaces (e.g., east and west) and then alternating (e.g., curtain v. interior) between floors. The HVAC system for the building is designed as a single zone system. The HVAC system was operating properly on the day of our inspection and was verified, by building maintenance personnel, to be supplying at least 12% outside (fresh) air to the system.

### ***Visual Assessment***

A fungal visual assessment was performed along the perimeter walls, ceilings and floors of the pre-selected floors to inspect for mold growth or other water damage. No visible mold growth was observed in any of the inspected floors. Water stains were observed on the numerous ceiling tiles along the perimeter walls (primarily south and west sides) of floors 2, 9, 11, and 22. Visual inspection photographs are available by request, if needed.

### ***Air Sampling Results***

***Fungal Air Sampling Protocols & Locations*** - The air sampling was performed with a Zefon high-volume vacuum pump at a flow rate of fifteen liters per minute (15 LPM) for a period of five (5) minutes in the following fifty-two (52) locations:

1. Ext, ground level, East, AM	19. 7 fl, North, curtain, N21/N18	37. 20th, North, open, N20
2. Ext, garage roof, South, AM	20. 7 fl, East, open, M18/L-18	38. 20th, West, curtain, L22/M22
3. Ext, ground level, North, AM	21. 9 fl, East, curtain, M18	39. 20th, South, open, K20
4. Ext, roof, helipad, AM	22. 9 fl, North, open, N-20	40. 20th, East, curtain, L18/M18
5. 2nd fl, South, curtain, rm 208	23. 9 fl, West, curtain, M22/L22	41. 22nd, South, curtain, K21/K22
6. 2nd fl, East, open, M-18/L-18	24. 9 fl, South, open, K-20	42. 22nd, West, open, near 2221
7. 2nd fl, North curtain, N20/N21	25. 11 fl, North, curtain, N20	43. 22nd, North, curtain, N21/N22
8. 2nd fl, West, open, M-22/M-23	26. 11 fl, East, open, L22/M22	44. 22nd, East, open, near rm 2235
9. 3rd fl, West, curtain, K-22	27. 11 fl, South, curtain, K20	45. 24th, North, open, N20
10. 3rd fl, South, open, K-20	28. 11 fl, West, open, L18/M18	46. 24th, East, curtain, rm 2445
11. 3rd fl, East, curtain, rm 311	29. 15th flr, West, curtain, M-22/L22	47. 24th, South, open, law lib
12. 3rd fl, North, open, elev/317	30. 15th flr, South, open, K20	48. 24th, West, curtain, rm 2423
13. Ext, ground level, North, MID	31. 15th, East, curtain, L-18/M-18	49. Ext, roof, helipad, PM
14. Ext, garage roof, South, MID	32. 15th, North, open, N20	50. Ext, ground level, North, PM
15. Ext, garage roof, West, MID	33. 18th, South, curtain, K20	51. Ext, garage roof, South, PM
16. Ext, roof, helipad, MID	34. 18th, East, open, L18-M18	52. Ext, ground level, East, PM
17. 7 fl, South curtain, K-20	35. 18th, North, curtain, N20	
18. 7 fl, West, open, L-22/M-22	36. 18th, West, open, L22	

A total of fifty-three (53) samples were collected: forty (40) interior, twelve (12) exterior and one (1) field blank. The exterior samples were collected before (AM), at mid-day (MID), and after (PM) the interior sampling so that the results of the interior samples could be compared to the exterior results. Industry practice and guidelines recommend the comparison of interior and exterior air sampling results. The interior results should be lower for the total airborne spore concentration and lower for the dominant genera in a building without fungal amplification.

**Total Airborne Fungal Results** - The exterior spore concentration range for the twelve samples were between 1,694 – 25,203 spores/m<sup>3</sup>. All interior samples in the building were at least two orders of magnitude lower than the average for the exterior (10,337 spores/m<sup>3</sup>).

**Dominant Airborne Genera Comparison** - The dominant genera ranking for most the exterior samples was *Basidiospores* (1<sup>st</sup>), *Ascospores* (2<sup>nd</sup>), and *Penicillium/Aspergillus* types or *Cladosporium* (3<sup>rd</sup>). Two of the exterior samples exhibited more variation in the second and third rank orders: *Basidiospores* (1<sup>st</sup>), *Cladosporium* (2<sup>nd</sup>) and *Ascospores* (3<sup>rd</sup>) or *Basidiospores* (1<sup>st</sup>), *Penicillium/Aspergillus* types (2<sup>nd</sup>) and *Cladosporium* (3<sup>rd</sup>).

The interior dominant genera rankings were different in several samples when compared with the exterior samples. However, the interior rank order variation was at spore levels which were below any corresponding exterior spore type concentrations. For example, the exterior *Penicillium/Aspergillus* average concentration was 374 spores/m<sup>3</sup> and was normally the second or third rank order. In sample #1799-107-5ST, collected from the 2<sup>nd</sup> floor, room 208, it was the first rank order with a concentration of 53 spores/m<sup>3</sup>. Thus, the interior concentration *Penicillium/Aspergillus* was less than 15% of the exterior average concentration.

Please see the attached laboratory reports, chain of custody forms, and EML's Mold Range™ (California and month specific exterior comparison data) for additional details. All samples were collected in accordance with established protocols and samples were submitted to Environmental Microbiological Laboratory, Inc. in San Bruno, CA under chain of custody.

### **Conclusions**

The historic water intrusion events in the building do not appear to have degraded the air quality of the employee occupied spaces as of the date of our sampling. All interior fungal spore concentrations in the building were at least two orders of magnitude lower than the average for the exterior. No visible mold growth was observed in any of the inspected floors. Water stains were observed on the numerous ceiling tiles along the perimeter walls (primarily south and west sides) of floors 2, 9, 11, and 22.

### ***Limitations and Qualifications***

1. The assessment performed by LCD does not include or cover the following matters: Matters that are subsequently discovered that could not have been reasonably foreseen or detected, using industry standards, during the performance of the assessment. Matters that could not have been discovered by LCD because of barriers, lack of access or other matters affecting accessibility. Matters that were not disclosed to LCD prior to, during or after the performance of the assessment. Any new deficiency that arose after the completion of the assessment by LCD.
2. To the extent that additional information becomes available to LCD, LCD reserves the right (without any obligation to do so) to modify its evaluation and/or this Report at any time based upon further review and analysis of any such additional information or data.
3. Certain items mentioned in the Report were performed by others not involving the supervision of, or management by, LCD, but were relied upon by LCD in making its evaluation and assessment.
4. The assessment performed by LCD is not meant or intended to supplement, modify or extinguish any warranty or representation made or given by third parties performing any of the recommended corrective work.
5. When consultation involves microbiological growth, or any assessment thereof, such microbiological growth may reoccur if the source of the growth is not remedied. All remediation of fungi in indoor environments can be inherently limited in the sense that conclusions are drawn and recommendations developed from information obtained from limited research and site evaluation. Except as may be noted in the assessment performed by LCD, subsurface areas, latent defects, or non-accessible areas and conditions were not field investigated and may differ from the conditions implied by the surface observations. Additionally, the passage of time may result in a change in the environmental characteristics at the subject property and the surrounding properties. No investigation or assessment can absolutely rule out the existence of any microbiological growth at any given site. LCD does not remediate or remedy sources of microbiological growth.
6. This Report and the assessment/survey conducted by LCD is prepared, and was performed, solely for the use and benefit of the client identified at the beginning of this Report. No other party may rely on this Report for any other purpose.

**Comments:**

\* Most of these spore types are not seen with culturable methods (Andersen sampling), although some may appear as non-sporulating fungi.

Most of the basidiospores are "mushroom" spores while the rusts and smuts are plant pathogens.

† The spores of *Aspergillus* and *Penicillium* (and others such as *Acremonium*, *Paecilomyces*) are small and round with very few distinguishing characteristics. They cannot be differentiated by non-viable sampling methods. Also, some species with very small spores are easily missed, and may be undercounted.

†† Background debris indicates the amount of non-biological particulate matter present on the trace (dust in the air) and the resulting visibility for the analyst. It is rated from 1+ (low) to 4+ (high). Counts from areas with 4+ background debris should be regarded as minimal counts and may be actually higher than reported. Background debris also affects the reporting limit for some spore types. The reporting limit is dependent on spore size, background debris, sample volume, and the percentage of the trace analyzed. It is important to account for sample volumes when evaluating dust levels. The minimum reporting limit is based on a raw count of one, which the lowest count that can be detected.

<b>TOTAL SPORES/M3</b>		<b>53</b>		<b>13</b>		<b>66</b>		<b>53</b>

**Comments:**

\* Most of these spore types are not seen with culturable methods (Andersen sampling), although some may appear as non-sporulating fungi. Most of the basidiospores are "mushroom" spores while the rusts and smuts are plant pathogens.

† The spores of *Aspergillus* and *Penicillium* (and others such as *Acremonium*, *Paecilomyces*) are small and round with very few distinguishing characteristics. They cannot be differentiated by non-viable sampling methods. Also, some species with very small spores are easily missed, and may be undercounted.

†† Background debris indicates the amount of non-biological particulate matter present on the trace (dust in the air) and the resulting visibility for the analyst. It is rated from 1+ (low) to 4+ (high). Counts from areas with 4+ background debris should be regarded as minimal counts and may be actually higher than reported. Background debris also affects the reporting limit for some spore types. The reporting limit is dependent on spore size, background debris, sample volume, and the percentage of the trace analyzed. It is important to account for sample volumes when evaluating dust levels. The minimum reporting limit is based on a raw count of one, which the lowest count that can be detected.

They cannot be differentiated by non-viable sampling methods. Also, some species with very small spores are easily missed, and may be undercounted.

†† Background debris indicates the amount of non-biological particulate matter present on the trace (dust in the air) and the resulting visibility for the analyst. It is rated from 1+ (low) to 4+ (high). Counts from areas with 4+ background debris should be regarded as minimal counts and may be actually higher than reported. Background debris also affects the reporting limit for some spore types. The reporting limit is dependent on spore size, background debris, sample volume, and the percentage of the trace analyzed. It is important to account for sample volumes when evaluating dust levels. The minimum reporting limit is based on a raw count of one, which the lowest count that can be detected.

‡ A "Version" greater than 1 indicates amended data.

<b>TOTAL SPORES/M3</b>	<b>21,069</b>								

† The Typical Outdoor Data by Date represents the typical outdoor spore levels across North America for the month indicated. The last column represents the frequency of occurrence. The low, medium, and high values represent the 2.5, 50, and 97.5 percentile values of the spore type when it is detected. For example, if the frequency of occurrence is 63% and the low value is 53, it would mean that the given spore type is detected 63% of the time and, when detected, 2.5% of the time it is present in levels above the detection limit and below 53 spores/m3. These values are updated periodically, and if enough data is not available to make a statistically meaningful assessment, it is indicated with a dash.

‡ The Typical Outdoor Data by Location represents the typical outdoor spore levels for the region indicated. As with the Typical Outdoor Data by Date, the four columns represent the frequency of occurrence and the typical low, medium, and high concentration values for the spore type indicated. These values are updated periodically, and if enough data is not available to make a statistically meaningful assessment, it is indicated with a dash.

\*The spores in this category are generally capable of growing on wet building materials in addition to growing outdoors. Building related growth is dependent upon the fungal type, moisture level, type of material, and other factors. *Cladosporium* is one of the predominant spore types worldwide and is frequently present in high numbers. *Penicillium/Aspergillus* species colonize both outdoor and indoor wet surfaces rapidly and are very easily dispersed. Other genera are usually present in lesser numbers.

\*\*These fungi are generally not found growing on wet building materials. For example, the rusts and smuts are obligate plant pathogens. However, in each group there are notable exceptions. For example, agents of wood decay are members of the basidiomycetes and high counts of a single morphological type of basidiospore on an inside sample should be considered significant.

Interpretation of the data contained in this report is left to the client or the persons who conducted the field work. This report is provided for informational and comparative purposes only and should not be relied upon for any other purpose. "Typical outdoor data" are based on the results of the analysis of samples delivered to and analyzed by Environmental Microbiology Laboratory, Inc. and assumptions regarding the origins of those samples. Sampling techniques, contaminants infecting samples, unrepresentative samples and other similar or dissimilar factors may affect these results. In addition, Environmental Microbiology Laboratory, Inc. may not have received and tested a representative number of samples for every region or time period. Environmental Microbiology Laboratory, Inc. hereby disclaims any liability for any and all direct, indirect, punitive, incidental, special or consequential damages arising out of the use or interpretation of the data contained in, or any actions taken or omitted in reliance upon, this report.

These values are updated periodically, and if enough data is not available to make a statistically meaningful assessment, it is indicated with a dash.

\*The spores in this category are generally capable of growing on wet building materials in addition to growing outdoors. Building related growth is dependent upon the fungal type, moisture level, type of material, and other factors. *Cladosporium* is one of the predominant spore types worldwide and is frequently present in high numbers. *Penicillium/Aspergillus* species colonize both outdoor and indoor wet surfaces rapidly and are very easily dispersed. Other genera are usually present in lesser numbers.

\*\*These fungi are generally not found growing on wet building materials. For example, the rusts and smuts are obligate plant pathogens. However, in each group there are notable exceptions. For example, agents of wood decay are members of the basidiomycetes and high counts of a single morphological type of basidiospore on an inside sample should be considered significant.

Interpretation of the data contained in this report is left to the client or the persons who conducted the field work. This report is provided for informational and comparative purposes only and should not be relied upon for any other purpose. "Typical outdoor data" are based on the results of the analysis of samples delivered to and analyzed by Environmental Microbiology Laboratory, Inc. and assumptions regarding the origins of those samples. Sampling techniques, contaminants infecting samples, unrepresentative samples and other similar or dissimilar factors may affect these results. In addition, Environmental Microbiology Laboratory, Inc. may not have received and tested a representative number of samples for every region or time period. Environmental Microbiology Laboratory, Inc. hereby disclaims any liability for any and all direct, indirect, punitive, incidental, special or consequential damages arising out of the use or interpretation of the data contained in, or any actions taken or omitted in reliance upon, this report.

† The Typical Outdoor Data by Date represents the typical outdoor spore levels across North America for the month indicated. The last column represents the frequency of occurrence. The low, medium, and high values represent the 2.5, 50, and 97.5 percentile values of the spore type when it is detected. For example, if the frequency of occurrence is 63% and the low value is 53, it would mean that the given spore type is detected 63% of the time and, when detected, 2.5% of the time it is present in levels above the detection limit and below 53 spores/m3. These values are updated periodically, and if enough data is not available to make a statistically meaningful assessment, it is indicated with a dash.

‡ The Typical Outdoor Data by Location represents the typical outdoor spore levels for the region indicated. As with the Typical Outdoor Data by Date, the four columns represent the frequency of occurrence and the typical low, medium, and high concentration values for the spore type indicated. These values are updated periodically, and if enough data is not available to make a statistically meaningful assessment, it is indicated with a dash.

† The Typical Outdoor Data by Date represents the typical outdoor spore levels across North America for the month indicated. The last column represents the frequency of occurrence. The low, medium, and high values represent the 2.5, 50, and 97.5 percentile values of the spore type when it is detected. For example, if the frequency of occurrence is 63% and the low value is 53, it would mean that the given spore type is detected 63% of the time and, when detected, 2.5% of the time it is present in levels above the detection limit and below 53 spores/m3. These values are updated periodically, and if enough data is not available to make a statistically meaningful assessment, it is indicated with a dash.

‡ The Typical Outdoor Data by Location represents the typical outdoor spore levels for the region indicated. As with the Typical Outdoor Data by Date, the four columns represent the frequency of occurrence and the typical low, medium, and high concentration values for the spore type indicated. These values are updated periodically, and if enough data is not available to make a statistically meaningful assessment, it is indicated with a dash.

\*The spores in this category are generally capable of growing on wet building materials in addition to growing outdoors. Building related growth is dependent upon the fungal type, moisture level, type of material, and other factors. *Cladosporium* is one of the predominant spore types worldwide and is frequently present in high numbers. *Penicillium/Aspergillus* species colonize both outdoor and indoor wet surfaces rapidly and are very easily dispersed. Other genera are usually present in lesser numbers.

\*\*These fungi are generally not found growing on wet building materials. For example, the rusts and smuts are obligate plant pathogens. However, in each group there are notable exceptions. For example, agents of wood decay are members of the basidiomycetes and high counts of a single morphological type of basidiospore on an inside sample should be considered significant.

Interpretation of the data contained in this report is left to the client or the persons who conducted the field work. This report is provided for informational and comparative purposes only and should not be relied upon for any other purpose. "Typical outdoor data" are based on the results of the analysis of samples delivered to and analyzed by Environmental Microbiology Laboratory, Inc. and assumptions regarding the origins of those samples. Sampling techniques, contaminants infecting samples, unrepresentative samples and other similar or dissimilar factors may affect these results. In addition, Environmental Microbiology Laboratory, Inc. may not have received and tested a representative number of samples for every region or time period. Environmental Microbiology Laboratory, Inc. hereby disclaims any liability for any and all direct, indirect, punitive, incidental, special or consequential damages arising out of the use or interpretation of the data contained in, or any actions taken or omitted in reliance upon, this report.
